Community Health Profile

**COMMUNITY HEALTH &
THE BUILT ENVIRONMENT**

INTRODUCTION

The Objective
This activity was designed to compile information about the health status and health decisions of community residents. The goal of this activity is to provide the community with community-specific health data that might contribute to decision-making for the purposes of improving physical activity and healthy eating behaviours. The community-specific information is compared to regional (former health region) and provincial levels.

The Canadian Communities Health Survey (CCHS)
The CCHS is a national health survey conducted periodically by Statistics Canada. Our analysis used data collected in 2007 and 2008 from over 130,000 respondents in more than 135 health regions across Canada. The survey gathers information related to health status, use of health care resources, and exposure to factors that increase or decrease an individual's risk for disease.

Our Approach to Analyzing the Data
The CCHS was designed to report data at the national, provincial and health region levels. Though the number of respondents across the country is large, the number of individuals responding in any single community can be quite small. As a result, estimates of community level health data can be very unreliable. For this reason, we used statistical methods to predict community levels based in part on: (1) the information from the community respondents; and, (2) the levels of respondents in the surrounding region and province.

Overview of this Document
This document is broken into two sections:

1) Summary Tables
> These tables contain a summary of the results from the analysis.   Results from the North Central Edmonton CCHS analysis are presented here in comparison with the results from the regional and provincial levels.

2) Detailed Results
> These tables include all of the data used to create the *Summary Tables*. A series of tables provide the actual and modeled proportions of respondents at the community, regional and provincial levels indicating a set of responses for all variables of interest. To assist in understanding these tables, a description of the analysis approach can be found on .

To assist in your navigation of this document, we have inserted links. These links are in blue font and are underlined. For example, if you would like to read the description of the analysis approach in the above paragraph, click on the link. After you have read the description, there will be a link on that page to bring you back here. In the *Summary Tables* section you will also find links to the more detailed results for each variable.   This will allow you to jump to any variable in the *Detailed Results* section for a closer examination, and then jump back again to the *Summary Table*. For each variable, there is one table in the *Summary Results* section and four tables in the *Detailed Results* section.

COMMUNITY HEALTH &
THE BUILT ENVIRONMENT

1) SUMMARY TABLES

Key

↑ = The Community Average is Probably Above the Regional/Provincial Average

━ = The Community Average is Likely Similar to the Regional/Provincial Average

↓ = The Community Average is Probably Below the Regional/Provincial Average

Percentage of respondents indicating their self-perceived health as: "Excellent" or "Very Good".

Gender	Age Group	Regional Comparison	Provincial Comparison
Female	18-34	–	↑
	35-64	–	↑
	65+	–	↑
Male	18-34	–	↑
	35-64	–	↑
	65+	–	↑

See detailed results…

Percentage of respondents indicating their self-perceived health compared to one year ago as: "Much Better" or "Somewhat Better".

Gender	Age Group	Regional Comparison	Provincial Comparison

**COMMUNITY HEALTH &
THE BUILT ENVIRONMENT**

2) DETAILED RESULTS

Overview

The detailed results for each variable are presented in four tables. These tables are broken down by gender and age group. Links to the Glossary of Terms section are provided for clarification of some concepts described in this section.

Table 1 includes the estimated percent of community residents indicating a given set of responses. The estimates are derived by process of: 1) weighting (i.e., "Weighted") or 2) modeling (i.e., "Modeled"). There is also a chance that we were unable to present an estimate. This is because the number of individuals indicating the response(s) was too low, and if we presented the number we would risk breaking an individual's confidentiality. If this is the case, we have omitted the estimate and its standard deviation from the table and indicated the variable is "Unreleasable". The check-boxes demonstrate if the estimate resulted from weighting or modeling, or if the estimate was determined to be unreleasable.

Table 2 presents comparisons between the community estimates and the estimates from the regional (former health region) and provincial respondents. These comparisons will indicate if each of the community estimates is "Lower", "Similar" or "Higher" than the regional or provincial estimates. These comparisons are based on the proportion of bootstraps of the community data found to be above the regional or provincial estimate. An additional advantage of the bootstrap process is that this comparison is still available when the actual estimate is unreleasable.

Table 3 is a look at the estimates for the Aspen Health Region. This table also includes a comparison between the regional estimates and the estimates from the province. As per the description for Table 1, the check-boxes demonstrate if the estimate resulted from weighting or modeling, or if the estimate was determined to be unreleasable.

Table 4 is a look at the actual estimates for the province. As per the description for Table 1, the check-boxes demonstrate if the estimate resulted from weighting or modeling, or if the estimate was determined to be unreleasable.

Tables 1, 3 and 4 report the standard error of the estimated percentages.

Key for the Bootstrap Comparisons

An identical Key to the one used for the Summary Tables is used here.

↑ = Probably Above the Regional/Provincial Estimate (>65% of bootstraps above estimate)
— = Likely Similar to the Regional/Provincial Estimate (45 - 65% of bootstraps above estimate)
↓ = Probably Below the Regional/Provincial Estimate (<45% of bootstraps above estimate)

Example of Table Descriptions

An example description is provided under each table for the first CCHS variable on pages 49-50.

COMMUNITY HEALTH &
THE BUILT ENVIRONMENT

Glossary of Terms

Weighting - CCHS Weighted Estimates ("Weighted")

In a survey, a sample of individuals is chosen to represent the larger population. Each particular individual may represent many others with similar characteristics. However, in complex surveys, the samples may not perfectly reflect the characteristics of the population. Thus, particular individuals may come to represent greater or fewer numbers of similar individuals. This is accomplished by assigning different weights to each individual's responses. Weights are assigned in such a way that, when combined, the estimates more accurately reflect the responses that would have been expected from the population overall. For example, if the sample included a smaller ratio of females to males than the population did, each female would be assigned a higher weight than each male to compensate for this under sampling.

Modeling – CCHS Modeled Estimates ("Modeled")

Unfortunately, for some groupings, information will have been collected on too few individuals to allow the publication of the weighted estimates (as this might result in a breach of confidentiality, i.e., because the data describes a relatively small geographic area, there is danger of releasing information that could, inadvertently, reveal a person's identity). In this case, a complex statistical procedure is used to combine information from the grouping with information from other groupings which are similar in order to generate an estimate that can be released. This requires that a model of who is similar to whom be adopted. For example, a weighted analysis might suggest an estimate cannot be released as there were too few females of a particular age indicating a given set of responses. A modeled estimate can be generated by including some information from females in the same age group from outside of the community, but from nearby communities that are found in the same region.   As the estimate is then calculated based on a larger sample size, the modeled estimate can be released while remaining an accurate reflection of this augmented group of individuals.

Bootstraps – CCHS Bootstrap Comparisons

Sometimes, even the modeled estimates will not be based on a large enough sample of individuals to allow them to be released. Here the computer is used to generate a large number of random samples from the original sample, and estimates are calculated for each of these re-samples. Each re-sample estimate is then compared to the estimate of the larger area (either region or province) and the number of times that the re-sample estimate exceeds the estimate for the region or province is tabulated. This allows statements like 'Probably Above the Regional Estimate' without providing enough information to breach confidentiality of any individual.

Standard Error

The standard error is a measure of how precise the estimate is likely to be, with smaller values indicating more a more precise estimate. If we were to repeat the survey many times, we would expect the actual percentage to be within the interval of approximately two times the estimated percentage 19 times out of 20.

COMMUNITY HEALTH &
THE BUILT ENVIRONMENT

Percentage of respondents indicating their self-perceived health as: "Excellent" or "Very Good".

Table 1. Community Estimates.

Gender	Age Group	Percentage of Respondents Indicating Given Response(s)				
		Percentage	Standard Error	Weighted	Modeled	Unreleasable
Female	18-34	70.7%	4.0%		√	
	35-64	63.5%	4.5%		√	
	65+	40.9%	4.7%		√	
Male	18-34	69.4%	4.2%		√	
	35-64	67.4%	11.9%	√		
	65+	39.3%	4.7%		√	

Based on our estimates, approximately 71% of females in the community between the ages of 18 and 34 perceive their health to be "Excellent" or "Very Good". The estimate was obtained using the data modeling process. The standard error is a measure of how precise the estimate is likely to be, with smaller values indicating more precise estimates.

Table 2. Percentage of Community Bootstraps above the Regional and Provincial Estimates.

Gender	Age Group	Regional Comparison		Provincial Comparison	
		Percentage Above	Comparison	Percentage Above	Comparison
Female	18-34	51.4%	–	69.6%	↑
	35-64	52.6%	–	69.4%	↑
	65+	52.0%	–	66.4%	↑
Male	18-34	51.0%	–	69.6%	↑
	35-64	52.0%	–	70.0%	↑
	65+	50.2%	–	66.0%	↑

For both genders and all age groups, the community estimates were found to be "Likely Similar to the Regional Estimate"(45 - 65% of bootstraps were above the provincial estimate). For both genders and all age groups, more than 45% of the bootstrap estimates were found to be above both the provincial estimates. Thus, all community estimates were determined to be "Probably Above the Regional Estimate".

COMMUNITY HEALTH &
THE BUILT ENVIRONMENT

Table 3. Regional Estimates, Including the Percentage of Regional Bootstraps above the Provincial Estimates.

Gender	Age Group	Percentage of Respondents Indicating Given Response(s)					Provincial Comparison	
		Percentage	Standard Error	Weighted	Modeled	Unreleasable	Percentage Above	Comparison
Female	18-34	69.0%	3.2%	√			85.2%	↑
	35-64	64.3%	2.7%	√			86.0%	↑
	65+	41.0%	3.8%	√			81.4%	↑
Male	18-34	70.4%	3.6%	√			86.0%	↑
	35-64	58.9%	2.8%	√			85.8%	↑
	65+	30.9%	3.9%	√			82.2%	↑

Based on our estimates, approximately 69% of females in the region between the ages of 18 and 34 perceive their health to be "Excellent" or "Very Good". The estimate was obtained using the data weighting process. The standard error is a measure of how precise the estimate is likely to be, with smaller values indicating more precise estimates. For both genders and all age groups, more than 65% of the bootstrap estimates were found to be above both the provincial estimates. Thus, all regional estimates were determined to be "Probably Above the Provincial Estimate".

Table 4. Provincial Estimates.

Gender	Age Group	Percentage of Respondents Indicating Given Response(s)				
		Percentage	Standard Error	Weighted	Modeled	Unreleasable
Female	18-34	69.3%	14.0%	√		
	35-64	65.4%	12.4%	√		
	65+	38.9%	5.0%		√	
Male	18-34	71.2%	18.9%	√		
	35-64	60.8%	12.5%	√		
	65+	37.3%	5.2%		√	

Based on our estimates, approximately 69% of females in the province between the ages of 18 and 34 perceive their health to be "Excellent" or "Very Good". The estimate was obtained using the data weighting process. The standard error is a measure of how precise the estimate is likely to be, with smaller values indicating more precise estimates.

**COMMUNITY HEALTH &
THE BUILT ENVIRONMENT**

Percentage of respondents indicating their self-perceived health compared to one year ago as: "Much Better" or "Somewhat Better".

Table 1. Community Estimates.

Gender	Age Group	Percentage of Respondents Indicating Given Response(s)				
		Percentage	Standard Error	Weighted	Modeled	Unreleasable
Female	18-34	32.8%	5.9%		√	
	35-64	19.5%	4.1%		√	
	65+	15.0%	3.5%		√	
Male	18-34	29.6%	5.7%		√	
	35-64	17.3%	3.7%		√	
	65+	13.2%	3.2%		√	

Table 2. Percentage of Community Bootstraps above the Regional and Provincial Estimates.

Gender	Age Group	Regional Comparison		Provincial Comparison	
		Percentage Above	Comparison	Percentage Above	Comparison
Female	18-34	78.6%	↑	63.0%	–
	35-64	79.0%	↑	60.2%	–
